# Graph Terminology

- ▶ A **Graph** is a collection of vertices, and edges between them

# Graph Terminology

- ▶ A **Graph** is a collection of vertices, and edges between them
- ▶ Edges are defined as the unique connection between two different vertices

# Graph Terminology

- ▶ A **Graph** is a collection of vertices, and edges between them
- ▶ Edges are defined as the unique connection between two different vertices
- ▶ The degree of a vertex in a graph is the number of edges that vertex is connected to

## Bipartite Graph

**Definition:** A Bipartite Graph is a graph such that every vertex can be put into one of two groups,  $V_1$  and  $V_2$ , with the property that all edges connect vertices in  $V_1$  to vertices in  $V_2$  (no edges go between vertices in the same group)

# Bipartite Graph

**Definition:** A Bipartite Graph is a graph such that every vertex can be put into one of two groups,  $V_1$  and  $V_2$ , with the property that all edges connect vertices in  $V_1$  to vertices in  $V_2$  (no edges go between vertices in the same group)

Example:

## Perfect Matching

**Definition:** A Perfect Matching is a bipartite graph such that there is exactly one edge connected to each vertex

## Perfect Matching

**Definition:** A Perfect Matching is a bipartite graph such that there is exactly one edge connected to each vertex

Example:

# The Problem

Problem: We are given a **Bipartite Graph**,  $G$ , with  $n$  vertices of degree  $d$  in sets  $V_1$  and  $V_2$

We are asked:

# The Problem

Problem: We are given a **Bipartite Graph**,  $G$ , with  $n$  vertices of degree  $d$  in sets  $V_1$  and  $V_2$

We are asked:

- ▶ Can we find  $d$  **Perfect Matchings** of  $G$ ?

# The Problem

Problem: We are given a **Bipartite Graph**,  $G$ , with  $n$  vertices of degree  $d$  in sets  $V_1$  and  $V_2$

We are asked:

- ▶ Can we find  $d$  **Perfect Matchings** of  $G$ ?
- ▶ How can we find these Perfect Matchings?

# The Problem

- ▶ Given:  $G$  is composed of two sets of vertices:  $V_1$  and  $V_2$  that each have  $n$  elements

# The Problem

- ▶ Given:  $G$  is composed of two sets of vertices:  $V_1$  and  $V_2$  that each have  $n$  elements
- ▶ We shall label the vertices in  $V_1$  the numbers  $1', 2', \dots, (n-1)', n'$

# The Problem

- ▶ Given:  $G$  is composed of two sets of vertices:  $V_1$  and  $V_2$  that each have  $n$  elements
- ▶ We shall label the vertices in  $V_1$  the numbers  $1', 2', \dots, (n-1)', n'$
- ▶ And label the vertices in  $V_2$  the numbers  $1, 2, \dots, (n-1), n$

# The Problem

This may seem like a trivial task but let us consider a simple case:

# The Problem

This may seem like a trivial task but let us consider a simple case:

# The Problem

If we randomly pick edges we could get the following:

## The Problem

If we randomly pick edges we could get the following:

- ▶ This is notably not a perfect matching, and we cannot easily make it one because there does not exist an edge in our initial graph from 2' to 1

## The Set Up

Let us consider the case when  $d=n$ ; there is an edge from every vertex in  $V_1$  to every vertex in  $V_2$ , and we can model this as a table:

## The Set Up

Let us consider the case when  $d=n$ ; there is an edge from every vertex in  $V_1$  to every vertex in  $V_2$ , and we can model this as a table:

Example: let  $d=n=4$

$1'$	$2'$	$3'$	$4'$
1	1	1	1
2	2	2	2
3	3	3	3
4	4	4	4

## The Set Up

Let us consider the case when  $d=n$ ; there is an edge from every vertex in  $V_1$  to every vertex in  $V_2$ , and we can model this as a table:

Example: let  $d=n=4$

- ▶ Each column is headed by a vertex in  $V_1$

## The Set Up

Let us consider the case when  $d=n$ ; there is an edge from every vertex in  $V_1$  to every vertex in  $V_2$ , and we can model this as a table:

Example: let  $d=n=4$

- ▶ Each column is headed by a vertex in  $V_1$
- ▶ Each other number in the column is a vertex in  $V_2$  such that there is an edge between the head of a column and each element in its column

## The Set Up

If instead of having our table represent  $d=n$  we wanted some other  $d$  less than  $n$ , we can do this by simply crossing off edges that are not present

# The Set Up

If instead of having our table represent  $d=n$  we wanted some other  $d$  less than  $n$ , we can do this by simply crossing off edges that are not present

Example:  $n=4$ ,  $d=2$

$1'$	$2'$	$3'$	$4'$
$X_1$	$X_1$	1	1
2	$X_2$	2	$X_2$
$X_3$	3	$X_3$	3
4	4	$X_4$	$X_4$

## The Set Up

If instead of having our table represent  $d=n$  we wanted some other  $d$  less than  $n$ , we can do this by simply crossing off edges that are not present

Example:  $n=4$ ,  $d=2$

$1'$	$2'$	$3'$	$4'$
$X_1$	$X_1$	1	1
2	$X_2$	2	$X_2$
$X_3$	3	$X_3$	3
4	4	$X_4$	$X_4$

For edges that we removed from the  $d=n$  graph, we put an X in the array to indicate that there is not an edge

# The Process

- ▶ We can take a bipartite graph with  $d$  edges and construct a table for it such that each column has  $d$  elements that are not-X's

# The Process

- ▶ We can take a bipartite graph with  $d$  edges and construct a table for it such that each column has  $d$  elements that are not-X's
- ▶ From here we shall start picking elements, in a specific fashion, to find a single perfect matching

# The Process

- ▶ We can take a bipartite graph with  $d$  edges and construct a table for it such that each column has  $d$  elements that are not-X's
- ▶ From here we shall start picking elements, in a specific fashion, to find a single perfect matching
- ▶ Once we find a perfect matching we can delete it from our graph to reduce  $d$  by 1,

# The Process

- ▶ We can take a bipartite graph with  $d$  edges and construct a table for it such that each column has  $d$  elements that are not-X's
- ▶ From here we shall start picking elements, in a specific fashion, to find a single perfect matching
- ▶ Once we find a perfect matching we can delete it from our graph to reduce  $d$  by 1, from which we can repeat the process  $d$  times until the entire initial graph becomes partitioned into  $d$  perfect matchings

# The Process

- ▶ We can take a bipartite graph with  $d$  edges and construct a table for it such that each column has  $d$  elements that are not-X's
- ▶ From here we shall start picking elements, in a specific fashion, to find a single perfect matching
- ▶ Once we find a perfect matching we can delete it from our graph to reduce  $d$  by 1, from which we can repeat the process  $d$  times until the entire initial graph becomes partitioned into  $d$  perfect matchings
- ▶ When we pick a vertex of  $V_2$  to draw an edge to a specific vertex in  $V_1$ ,

# The Process

- ▶ We can take a bipartite graph with  $d$  edges and construct a table for it such that each column has  $d$  elements that are not-X's
- ▶ From here we shall start picking elements, in a specific fashion, to find a single perfect matching
- ▶ Once we find a perfect matching we can delete it from our graph to reduce  $d$  by 1, from which we can repeat the process  $d$  times until the entire initial graph becomes partitioned into  $d$  perfect matchings
- ▶ When we pick a vertex of  $V_2$  to draw an edge to a specific vertex in  $V_1$ , we cannot not pick another edge that shares either of these two vertices

# The Process

- ▶ We can take a bipartite graph with  $d$  edges and construct a table for it such that each column has  $d$  elements that are not- $X$ 's
- ▶ From here we shall start picking elements, in a specific fashion, to find a single perfect matching
- ▶ Once we find a perfect matching we can delete it from our graph to reduce  $d$  by 1, from which we can repeat the process  $d$  times until the entire initial graph becomes partitioned into  $d$  perfect matchings
- ▶ When we pick a vertex of  $V_2$  to draw an edge to a specific vertex in  $V_1$ , we cannot not pick another edge that shares either of these two vertices
- ▶ On the table this corresponds to picking an element,  $E$ , in a column,  $C'$ , and then not picking another element  $E$  in a different column

# The Process

- ▶ We can take a bipartite graph with  $d$  edges and construct a table for it such that each column has  $d$  elements that are not- $X$ 's
- ▶ From here we shall start picking elements, in a specific fashion, to find a single perfect matching
- ▶ Once we find a perfect matching we can delete it from our graph to reduce  $d$  by 1, from which we can repeat the process  $d$  times until the entire initial graph becomes partitioned into  $d$  perfect matchings
- ▶ When we pick a vertex of  $V_2$  to draw an edge to a specific vertex in  $V_1$ , we cannot not pick another edge that shares either of these two vertices
- ▶ On the table this corresponds to picking an element,  $E$ , in a column,  $C'$ , and then not picking another element  $E$  in a different column and likewise not pick another element from column  $C'$

# The Process

- ▶ The last, and most important step, is determining which points to pick

## The Process

- ▶ The last, and most important step, is determining which points to pick
- ▶ To answer this we shall define a  $K_c$  to be the number of elements in a column  $C'$  that are not  $X$ ,

## The Process

- ▶ The last, and most important step, is determining which points to pick
- ▶ To answer this we shall define a  $K_c$  to be the number of elements in a column  $C'$  that are not  $X$ ,
- ▶ If we consider all of the columns, then we will pick any element from the column with the smallest value for  $K_c$

## The Process

- ▶ The last, and most important step, is determining which points to pick
- ▶ To answer this we shall define a  $K_c$  to be the number of elements in a column  $C'$  that are not  $X$ ,
- ▶ If we consider all of the columns, then we will pick any element from the column with the smallest value for  $K_c$

To best understand this process, let us find a perfect matching of the previous example:

$1'$	$2'$	$3'$	$4'$
$X_1$	$X_1$	1	1
2	$X_2$	2	$X_2$
$X_3$	3	$X_3$	3
4	4	$X_4$	$X_4$

# The Process

To best understand this process, let us find a perfect matching of the previous example:

$1'$	$2'$	$3'$	$4'$
$X_1$	$X_1$	1	1
2	$X_2$	2	$X_2$
$X_3$	3	$X_3$	3
4	4	$X_4$	$X_4$

As  $K_c = 2$  for all the columns we can pick a random element from any of the columns, let us then arbitrarily pick column 2' element 3

# The Process

Thus having picked  $(2',3)$  we shall make all other elements in column  $2'$  and row  $3 X$ :

$1'$	$2'$	$3'$	$4'$
$X_1$	$X_1$	1	1
2	$X_2$	2	$X_2$
$X_3$	3	$X_3$	3
4	4	$X_4$	$X_4$

# The Process

Thus having picked  $(2',3)$  we shall make all other elements in column  $2'$  and row  $3 X$ :

$1'$	$2'$	$3'$	$4'$
$X_1$	$X_1$	1	1
2	$X_2$	2	$X_2$
$X_3$	3	$X_3$	$X_3$
4	$X_4$	$X_4$	$X_4$

# The Process

There are now three rows left.  $K_1 = K_3 = 2$  while  $K_4 = 1$  thus we must pick from column 4' the element 1

$1'$	$2'$	$3'$	$4'$
$X_1$	$X_1$	1	1
2	$X_2$	2	$X_2$
$X_3$	3	$X_3$	$X_3$
4	$X_4$	$X_4$	$X_4$

# The Process

Having picked  $(4',1)$  we must now X out all other elements in Column  $4'$  and row 1:

$1'$	$2'$	$3'$	$4'$
$X_1$	$X_1$	1	1
2	$X_2$	2	$X_2$
$X_3$	3	$X_3$	$X_3$
4	$X_4$	$X_4$	$X_4$

# The Process

Having picked  $(4',1)$  we must now X out all other elements in Column  $4'$  and row 1:

$1'$	$2'$	$3'$	$4'$
$X_1$	$X_1$	$X_1$	1
2	$X_2$	2	$X_2$
$X_3$	3	$X_3$	$X_3$
4	$X_4$	$X_4$	$X_4$

# The Process

We now have that  $K_1 = 2$  and  $K_3 = 1$  so we must pick from column 3' element 2:

1'	2'	3'	4'
$X_1$	$X_1$	$X_1$	1
2	$X_2$	2	$X_2$
$X_3$	3	$X_3$	$X_3$
4	$X_4$	$X_4$	$X_4$

# The Process

Putting X's in the appropriate places yields:

1'	2'	3'	4'
$X_1$	$X_1$	$X_1$	1
2	$X_2$	2	$X_2$
$X_3$	3	$X_3$	$X_3$
4	$X_4$	$X_4$	$X_4$

1'	2'	3'	4'
$X_1$	$X_1$	$X_1$	1
$X_2$	$X_2$	2	$X_2$
$X_3$	3	$X_3$	$X_3$
4	$X_4$	$X_4$	$X_4$

Leaving only element  $(1',4)$  to pick. The edges defined by  $(1',4)$ ,  $(2',3)$ ,  $(3',2)$ , and  $(4',1)$  thus form a perfect matching:

# The Proof

Claim: That the process detailed above will give a perfect matching

# The Proof

Claim: That the process detailed above will give a perfect matching  
We will prove this by contradiction

# The Proof

Claim: That the process detailed above will give a perfect matching

We will prove this by contradiction

- ▶ This process will always give some matching, but if this matching wasn't perfect, there would be some vertices without edges

# The Proof

Claim: That the process detailed above will give a perfect matching  
We will prove this by contradiction

- ▶ This process will always give some matching, but if this matching wasn't perfect, there would be some vertices without edges
- ▶ The only way this would happen in the process is if some  $K_{A_0}$  were to become 0 (such that we did not yet pick an element from column  $A'_0$ )

## The Proof

Claim: That the process detailed above will give a perfect matching  
We will prove this by contradiction

- ▶ This process will always give some matching, but if this matching wasn't perfect, there would be some vertices without edges
- ▶ The only way this would happen in the process is if some  $K_{A_0}$  were to become 0 (such that we did not yet pick an element from column  $A'_0$ )
- ▶ If we look at the step in the process before  $K_{A_0} = 0$  then column  $A_0$  must have had an element,  $e_0$

## The Proof

Claim: That the process detailed above will give a perfect matching  
We will prove this by contradiction

- ▶ This process will always give some matching, but if this matching wasn't perfect, there would be some vertices without edges
- ▶ The only way this would happen in the process is if some  $K_{A_0}$  were to become 0 (such that we did not yet pick an element from column  $A'_0$ )
- ▶ If we look at the step in the process before  $K_{A_0} = 0$  then column  $A_0$  must have had an element,  $e_0$
- ▶ Because we must pick from the column with the fewest elements to pick from,

## The Proof

Claim: That the process detailed above will give a perfect matching  
We will prove this by contradiction

- ▶ This process will always give some matching, but if this matching wasn't perfect, there would be some vertices without edges
- ▶ The only way this would happen in the process is if some  $K_{A_0}$  were to become 0 (such that we did not yet pick an element from column  $A'_0$ )
- ▶ If we look at the step in the process before  $K_{A_0} = 0$  then column  $A_0$  must have had an element,  $e_0$
- ▶ Because we must pick from the column with the fewest elements to pick from, the only reason we would not have select  $(A'_0, e_0)$  would be if there were another column,  $A'_1$ , that also only had one element,  $e_1$ , left to pick

## The Proof

Claim: That the process detailed above will give a perfect matching  
We will prove this by contradiction

- ▶ This process will always give some matching, but if this matching wasn't perfect, there would be some vertices without edges
- ▶ The only way this would happen in the process is if some  $K_{A_0}$  were to become 0 (such that we did not yet pick an element from column  $A'_0$ )
- ▶ If we look at the step in the process before  $K_{A_0} = 0$  then column  $A_0$  must have had an element,  $e_0$
- ▶ Because we must pick from the column with the fewest elements to pick from, the only reason we would not have select  $(A'_0, e_0)$  would be if there were another column,  $A'_1$ , that also only had one element,  $e_1$ , left to pick
- ▶ And specifically the only reason  $(A'_1, e_1)$  would prevent  $(A'_0, e_0)$  from getting chosen is if  $e_1 = e_0$  so as to then change  $e_0$  to an X

# The Proof

- ▶ If we now look at the pick that lead to  $K_{A_0} = K_{A_1} = 1$  then the columns  $A'_0$  and  $A'_1$  must've had a second element in them.

# The Proof

- ▶ If we now look at the pick that lead to  $K_{A_0} = K_{A_1} = 1$  then the columns  $A'_0$  and  $A'_1$  must've had a second element in them.
- ▶ We get that the only reason we would not have selected either  $(A'_0, a_0)$  or  $(A'_1, a_1)$  is if there was a third column,  $A'_2$  that had also had at most two elements left.

# The Proof

- ▶ If we now look at the pick that lead to  $K_{A_0} = K_{A_1} = 1$  then the columns  $A'_0$  and  $A'_1$  must've had a second element in them.
- ▶ We get that the only reason we would not have selected either  $(A'_0, a_0)$  or  $(A'_1, a_1)$  is if there was a third column,  $A'_2$  that had also had at most two elements left.
- ▶ For  $A'_2$  to be selected and leave behind the situation we had above (going one step back from  $K_{A_1} = 0$ ) we get that all three columns must've shared an element that was selected in column  $A'_2$ , and we shall call this element  $e_2$

## The Proof

- ▶ If we continue this process going  $P$  picks back from  $K_{A_1} = 0$  we are considering  $P+1$  columns,  $A_0, A_1, \dots, A_p$ , each of which has  $P$  elements to choose from

## The Proof

- ▶ If we continue this process going  $P$  picks back from  $K_{A_1} = 0$  we are considering  $P+1$  columns,  $A_0, A_1, \dots, A_p$ , each of which has  $P$  elements to choose from
- ▶ We also get that these  $P+1$  rows must share at least one element in common so as to lead to the scenario of  $P-1$  picks away from  $K_{A_1} = 0$

# The Proof

- ▶ If we continue this process going  $P$  picks back from  $K_{A_1} = 0$  we are considering  $P+1$  columns,  $A_0, A_1, \dots, A_p$ , each of which has  $P$  elements to choose from
- ▶ We also get that these  $P+1$  rows must share at least one element in common so as to lead to the scenario of  $P-1$  picks away from  $K_{A_1} = 0$
- ▶ If we let  $P=n-d$  then we arrive at the fact that there are  $(n-d)+1$  rows that have at least 1 element,  $E$ , in common from which to choose

# The Proof

- ▶ If we continue this process going  $P$  picks back from  $K_{A_1} = 0$  we are considering  $P+1$  columns,  $A_0, A_1, \dots, A_p$ , each of which has  $P$  elements to choose from
- ▶ We also get that these  $P+1$  rows must share at least one element in common so as to lead to the scenario of  $P-1$  picks away from  $K_{A_1} = 0$
- ▶ If we let  $P=n-d$  then we arrive at the fact that there are  $(n-d)+1$  rows that have at least 1 element,  $E$ , in common from which to choose
- ▶ However we have only removed  $d$  edges from our the base graph  $d=n$

# The Proof

- ▶ If we continue this process going  $P$  picks back from  $K_{A_1} = 0$  we are considering  $P+1$  columns,  $A_0, A_1, \dots, A_p$ , each of which has  $P$  elements to choose from
- ▶ We also get that these  $P+1$  rows must share at least one element in common so as to lead to the scenario of  $P-1$  picks away from  $K_{A_1} = 0$
- ▶ If we let  $P=n-d$  then we arrive at the fact that there are  $(n-d)+1$  rows that have at least 1 element,  $E$ , in common from which to choose
- ▶ However we have only removed  $d$  edges from our the base graph  $d=n$  which means that each element is removed  $d$  times across all of the columns, thus each row has an element appear  $n-d$  times,

# The Proof

- ▶ If we continue this process going  $P$  picks back from  $K_{A_1} = 0$  we are considering  $P+1$  columns,  $A_0, A_1, \dots, A_p$ , each of which has  $P$  elements to choose from
- ▶ We also get that these  $P+1$  rows must share at least one element in common so as to lead to the scenario of  $P-1$  picks away from  $K_{A_1} = 0$
- ▶ If we let  $P=n-d$  then we arrive at the fact that there are  $(n-d)+1$  rows that have at least 1 element,  $E$ , in common from which to choose
- ▶ However we have only removed  $d$  edges from our the base graph  $d=n$  which means that each element is removed  $d$  times across all of the columns, thus each row has an element appear  $n-d$  times, but we now have a row,  $E$ , can be chosen by  $n-d+1$  columns, thus

## The Proof

- ▶ If we continue this process going  $P$  picks back from  $K_{A_1} = 0$  we are considering  $P+1$  columns,  $A_0, A_1, \dots, A_p$ , each of which has  $P$  elements to choose from
- ▶ We also get that these  $P+1$  rows must share at least one element in common so as to lead to the scenario of  $P-1$  picks away from  $K_{A_1} = 0$
- ▶ If we let  $P=n-d$  then we arrive at the fact that there are  $(n-d)+1$  rows that have at least 1 element,  $E$ , in common from which to choose
- ▶ However we have only removed  $d$  edges from our the base graph  $d=n$  which means that each element is removed  $d$  times across all of the columns, thus each row has an element appear  $n-d$  times, but we now have a row,  $E$ , can be chosen by  $n-d+1$  columns, thus WE HAVE A CONTRADICTION!

## The Proof

- ▶ If we continue this process going  $P$  picks back from  $K_{A_1} = 0$  we are considering  $P+1$  columns,  $A_0, A_1, \dots, A_p$ , each of which has  $P$  elements to choose from
- ▶ We also get that these  $P+1$  rows must share at least one element in common so as to lead to the scenario of  $P-1$  picks away from  $K_{A_1} = 0$
- ▶ If we let  $P=n-d$  then we arrive at the fact that there are  $(n-d)+1$  rows that have at least 1 element,  $E$ , in common from which to choose
- ▶ However we have only removed  $d$  edges from our the base graph  $d=n$  which means that each element is removed  $d$  times across all of the columns, thus each row has an element appear  $n-d$  times, but we now have a row,  $E$ , can be chosen by  $n-d+1$  columns, thus WE HAVE A CONTRADICTION!
- ▶ This means that the process detailed in this presentation will always yield a perfect matching

# Applications

**Definition:** A Latin Square is an  $n$  by  $n$  array that has each of  $n$  symbols appear exactly once in each row and each column

## Applications

**Definition:** A Latin Square is an  $n$  by  $n$  array that has each of  $n$  symbols appear exactly once in each row and each column

Example of a 5 by 5 Latin Square:

1	2	3	4	5
2	4	5	1	3
3	5	4	2	1
4	3	1	5	2
5	1	2	3	4

## Applications

**Definition:** A Latin Square is an  $n$  by  $n$  array that has each of  $n$  symbols appear exactly once in each row and each column

Example of a 5 by 5 Latin Square:

1	2	3	4	5
2	4	5	1	3
3	5	4	2	1
4	3	1	5	2
5	1	2	3	4

**Definition:** A Latin Rectangle is a partial Latin Square that has the first  $D$  rows given and the rest blank

## Applications

**Definition:** A Latin Square is an  $n$  by  $n$  array that has each of  $n$  symbols appear exactly once in each row and each column

Example of a 5 by 5 Latin Square:

1	2	3	4	5
2	4	5	1	3
3	5	4	2	1
4	3	1	5	2
5	1	2	3	4

**Definition:** A Latin Rectangle is a partial Latin Square that has the first  $D$  rows given and the rest blank

Example of a 2 by 4 Latin Rectangle:

1	2	3	4
2	4	5	1

# Application

We can complete a Latin Rectangle, by application of the process used to find perfect matchings, in the follow way:

# Application

We can complete a Latin Rectangle, by application of the process used to find perfect matchings, in the follow way:

Bipartite Graph Features	Analogous Features of Latin Squares
-----------------------------	--

# Application

We can complete a Latin Rectangle, by application of the process used to find perfect matchings, in the follow way:

Bipartite Graph Features	Analogous Features of Latin Squares
Each vertex in $V_1$	One specific Column

# Application

We can complete a Latin Rectangle, by application of the process used to find perfect matchings, in the follow way:

Bipartite Graph Features	Analogous Features of Latin Squares
Each vertex in $V_1$	One specific Column
Each vertex in $V_2$	One specific symbol

# Application

We can complete a Latin Rectangle, by application of the process used to find perfect matchings, in the follow way:

Bipartite Graph Features	Analogous Features of Latin Squares
Each vertex in $V_1$	One specific Column
Each vertex in $V_2$	One specific symbol
Each perfect matching	One specific row

## Application

We can complete a Latin Rectangle, by application of the process used to find perfect matchings, in the follow way:

Bipartite Graph Features	Analogous Features of Latin Squares
Each vertex in $V_1$	One specific Column
Each vertex in $V_2$	One specific symbol
Each perfect matching	One specific row
The common degree of all vertices	The number of blank rows

## Application

We can complete a Latin Rectangle, by application of the process used to find perfect matchings, in the follow way:

Bipartite Graph Features	Analogous Features of Latin Squares
Each vertex in $V_1$	One specific Column
Each vertex in $V_2$	One specific symbol
Each perfect matching	One specific row
The common degree of all vertices	The number of blank rows

As we can create  $d$  perfect matchings of a Bipartite Graph, we can complete the Latin Rectangle
